MATERIALS SCIENCE

Japanese Latecomer Joins Race To Build a Hard X-ray Laser

X-ray free-electron lasers are the next big thing in high-energy probes of matter. With U.S. and European machines in the works, Japan wants into the club

SAYO, HYOGO PREFECTURE, JAPAN—It's the scientific version of keeping up with the Joneses. Once researchers in one region plan a big, new experimental device, researchers everywhere want their own. The latest example: x-ray free-electron lasers (XFELs), which promise beams that are vastly brighter and with higher energy and shorter pulses than today's workhorse synchrotron x-rays.

These "hard" x-ray wavelengths—down to 0.1 nanometer—promise to reveal the struc-

broad interest for science, it is no surprise that [researchers] in three regions of the world want to have a facility of their own," says Reinhard Brinkmann, who leads the European effort based at the German Electron Synchrotron (DESY) research center in Hamburg. "Free-electron lasers are amazing things which herald a new era in photon science," says Janos Hajdu, a synchrotron radiation specialist at Uppsala University in Sweden.

XFELs rely on new approaches to gener-

or oscillating in lockstep—a quality missing from synchrotron light.

Although all three planned systems share the same basic setup, subtle differences give each of them strengths and weaknesses. "The final targets of the XFEL projects are the same, but the means are different," says Tsumoru Shintake, who heads accelerator development for Japan's XFEL.

The first project to come online will be Stanford's LCLS. Much of the key research underpinning XFELs was done at SLAC beginning in the early 1990s. And SLAC got a head start by using a 1-kilometer stretch of its now-idled linear accelerator, or linac. The SLAC group estimates that reusing its linac has saved more than \$300 million, giving a total construction cost of \$379 million. LCLS will have one undulator providing hard and soft x-rays to up to six experimental stations. Galayda says the group expects to generate its first x-rays by July 2008 and to start experiments by March 2009.

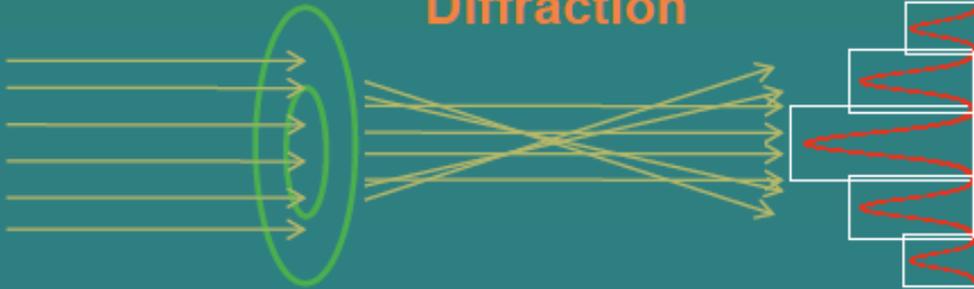

Japan's entry is the SPring-8 Compact SASE Source (SCSS), just now getting under construction here. Latecomers to the field, the team is using some homegrown technology to cut cost and size. "We're taking the first step toward making XFELs smaller and cheaper so more [institutions] can consider developing their own," boasts SCSS project leader Tetsuya Ishikawa. Whereas the other two machines will generate electrons by firing a laser at a metal target, **the SCSS heats a cathode to produce electrons. Eliminating the laser simplifies the system but requires careful compression of the cloud of electrons before they go into the linac.**

The wavelength of the output x-rays is a tradeoff between the energy of the electrons

	Nominal	4.5 mm
Maximum Attractive Force	~ 6 ton	

Why we are constructing XFELs?

- Realize dream of laser at X-ray wavelength.
- Very high peak power 2 GW, high photon flux.
- Very short pulse length. < 100 fsec
- Widely tunable wavelength.

Peak Brilliance Evolution

■ Peak brilliance will be enhanced by factor of 10^{10} from 3rd generation SR to XFEL.

■ $10^{10} = 10^1 \times 10^1 \times 10^1 \times 10^7$

= peak current by factor 10
x lowered emittance by 10
x energy spread lowered by 10
x **interference effect** 10^7 by micro-bunching formation.

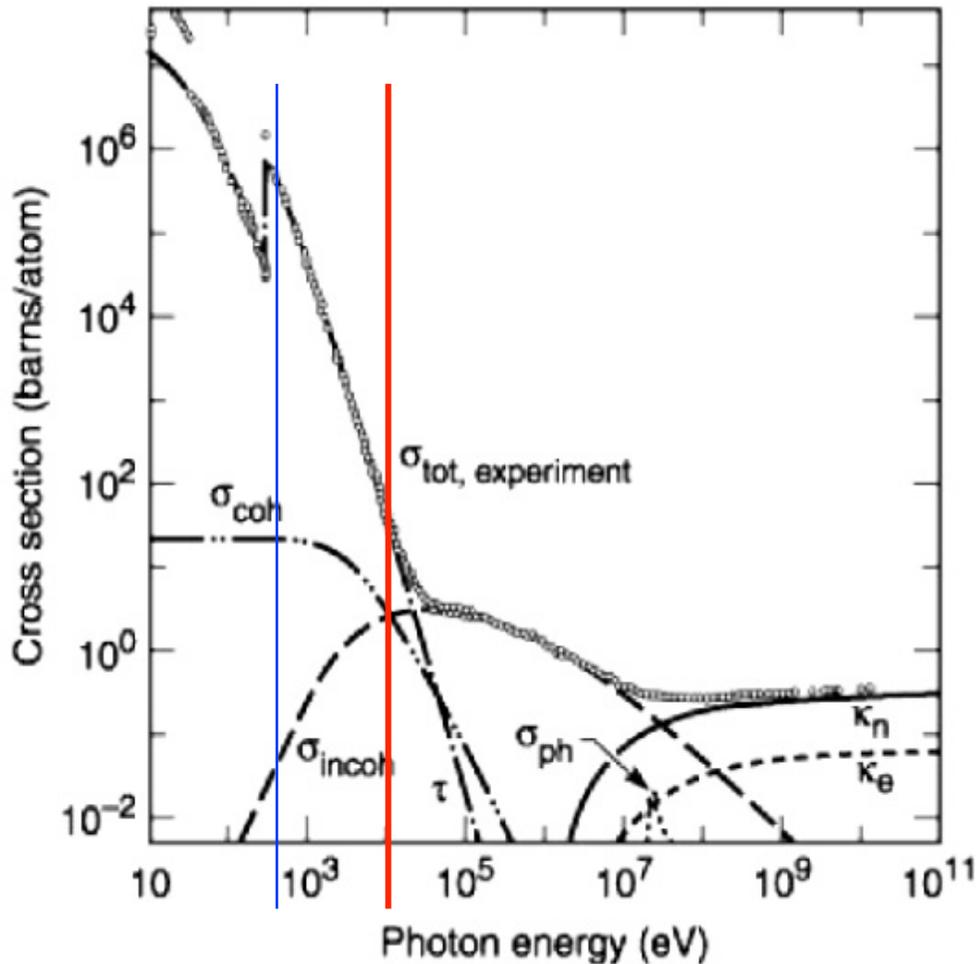

XFEL Radiation Characteristics

- **High Peak Power ~ GW**
 - high field **non linear physics**
 - high flux photons for single shot diffraction imaging
single molecular structural analysis

- **Short Pulse 10 ~ 100 fsec**
 - Time resolving experiment (Pump probe)
Chemical reaction

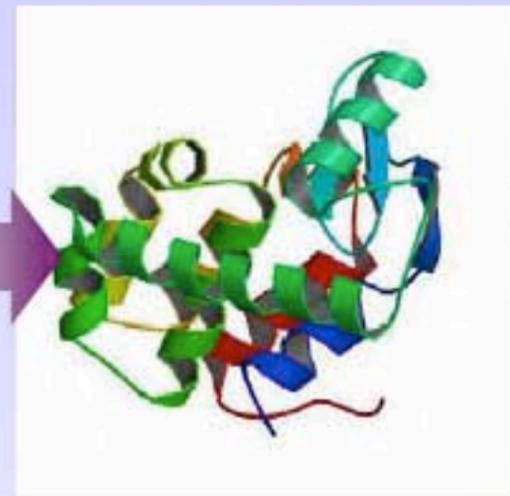

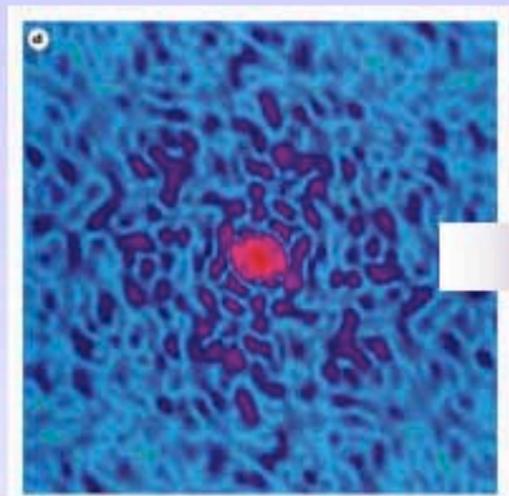

- **Coherent**
 - **Holography, Coherent Imaging**

Why 1 Angstrom?

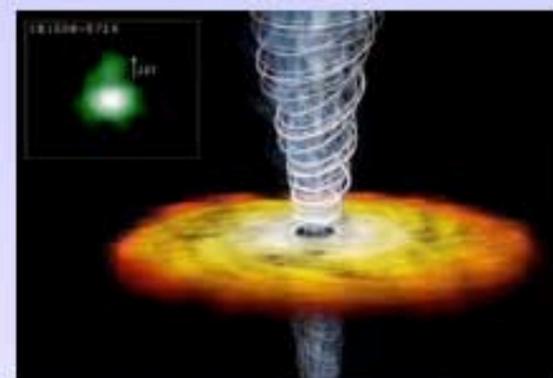

- Photo-ionization becomes lower as X-ray energy.
- Around 1 Å, 8 keV, photo-ionization becomes low enough to see coherent scattering.
- Spatial resolution becomes a few Angstrom, which resolves macromolecular crystal in biology.
→ Imaging, crystallography
- **water window** (2.3-4.4nm light) is also another candidate.
(a few micron-meter thick water)

Possibility of single biomolecule imaging with coherent amplification of weak scattering x-ray photons

Tsumoru Shintake

RIKEN SPring-8 Center, Harima Institute, 1-1-1 Kouto, Sayo, Hyogo 679-5148, Japan

(Received 23 April 2008; revised manuscript received 21 August 2008; published 3 October 2008)

The number of photons produced by coherent x-ray scattering from a single biomolecule is very small because of its extremely small elastic-scattering cross section and low damage threshold. Even with a high x-ray flux of 3×10^{12} photons per 100-nm-diameter spot and an ultrashort pulse of 10 fs driven by a future x-ray free electron laser (x-ray FEL), it has been predicted that **only a few 100 photons** will be produced from the scattering of a single lysozyme molecule. In observations of scattered x rays on a detector, the transfer of energy from wave to matter is accompanied by the quantization of the photon energy. Unfortunately, x rays have a high photon energy of 12 keV at wavelengths of 1 Å, which is required for atomic resolution imaging. Therefore, the number of photoionization events is small, which limits the resolution of imaging of a single biomolecule. **In this paper, I propose a method: instead of directly observing the photons scattered from the sample, we amplify the scattered waves by superimposing an intense coherent reference pump wave** on it and record the resulting interference pattern on a planar x-ray detector. Using a nanosized gold particle as a reference pump wave source, we can collect **10^4 – 10^5 photons** in single shot imaging where the signal from a single biomolecule is amplified and recorded as two-dimensional diffraction intensity data. An iterative phase retrieval technique can be used to recover the phase information and reconstruct the image of the single biomolecule and the gold particle at the same time. In order to precisely reconstruct a faint image of the single biomolecule in Angstrom resolution, whose intensity is much lower than that of the bright gold particle, I propose a technique that combines iterative phase retrieval on the reference pump wave and the digital Fourier transform holography on the sample. By using a large number of holography data, the three-dimensional electron density map can be assembled.

Physical Origin of Difficulty

- In observations of scattered X-rays on a detector, the transfer of energy from wave to matter is accompanied by the quantization of the photon energy. Unfortunately, X-rays have a considerably high photon energy of **12 keV** at wavelengths of 1 Å, which is required for atomic resolution imaging.
- Therefore, the number of photoionization events is considerably less, which limits the resolution of the imaging of a single biomolecule.

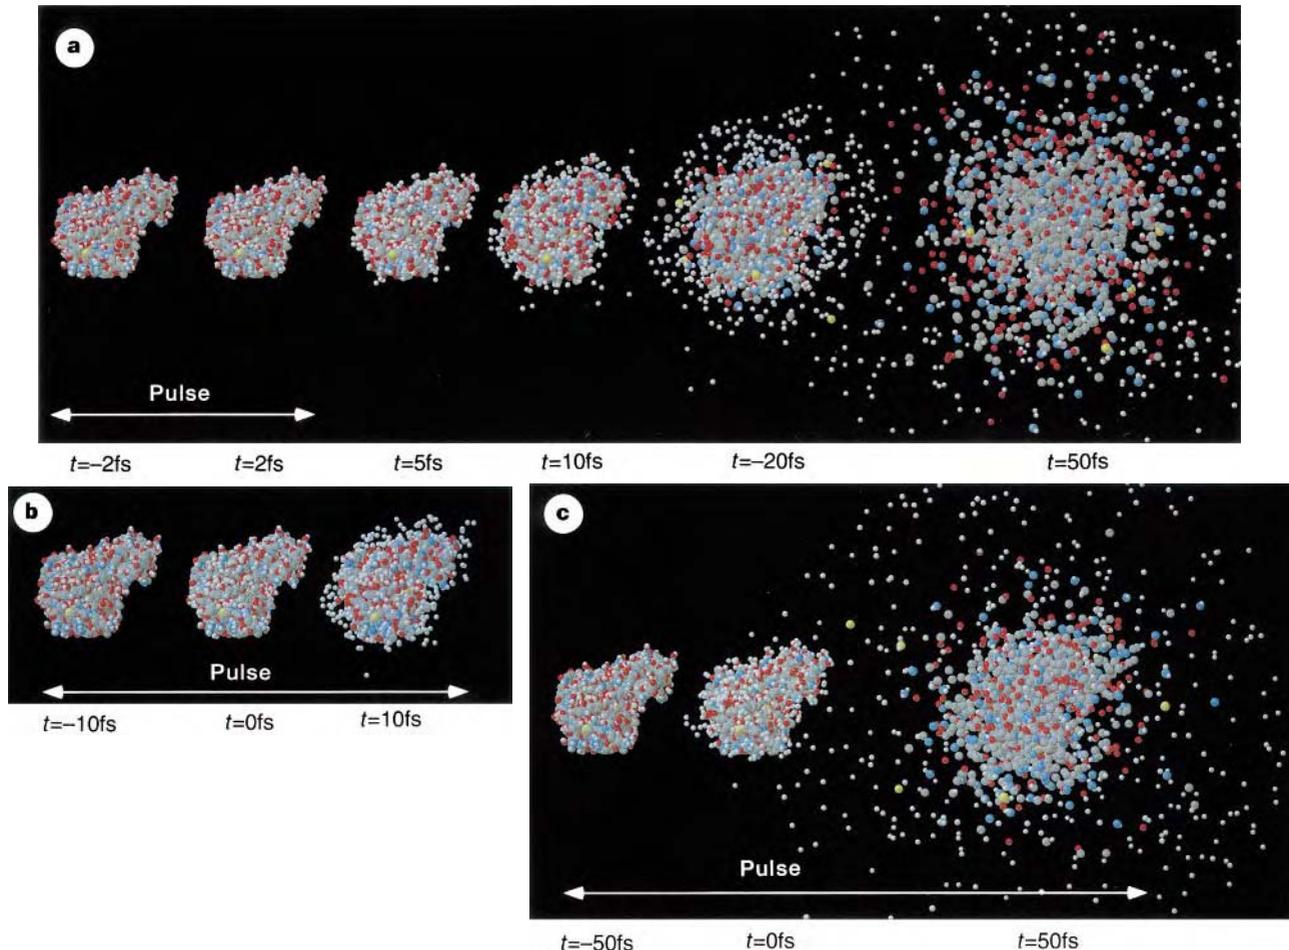

Figure 2 Explosion of T4 lysozyme (white, H; grey, C; blue, N; red, O; yellow, S) induced by radiation damage. The integrated X-ray intensity was 3×10^{12} (12 keV) photons per 100-nm diameter spot (3.8×10^6 photons per \AA^2) in all cases. **a**, A protein exposed to an X-ray pulse with an FWHM of 2 fs, and disintegration followed in time. Atomic positions in the first two structures (before and after the pulse) are practically identical at this pulse length

because of an inertial delay in the explosion. $R_{\text{nucI}} = 3\%$, $R_{\text{elec}} = 11\%$ **b**, Lysozyme exposed to the same number of photons as in **a**, but the FWHM of the pulse was 10 fs. Images show the structure at the beginning, in the middle and near the end of the X-ray pulse. $R_{\text{nucI}} = 7\%$, $R_{\text{elec}} = 12\%$ **c**, Behaviour of the protein during an X-ray pulse with a FWHM of 50 fs. $R_{\text{nucI}} = 26\%$, $R_{\text{elec}} = 30\%$.

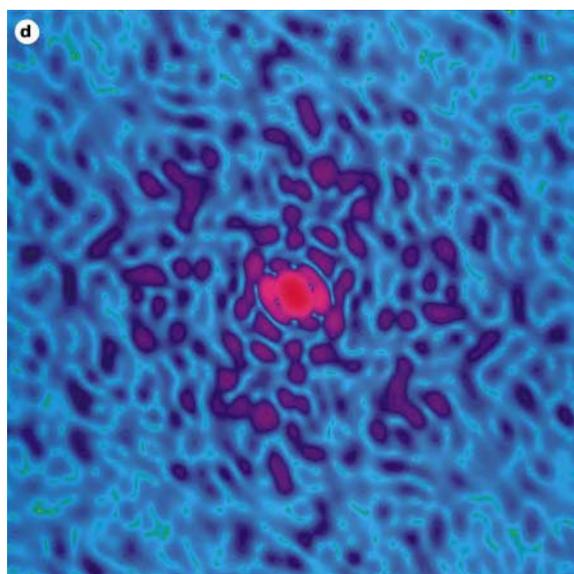

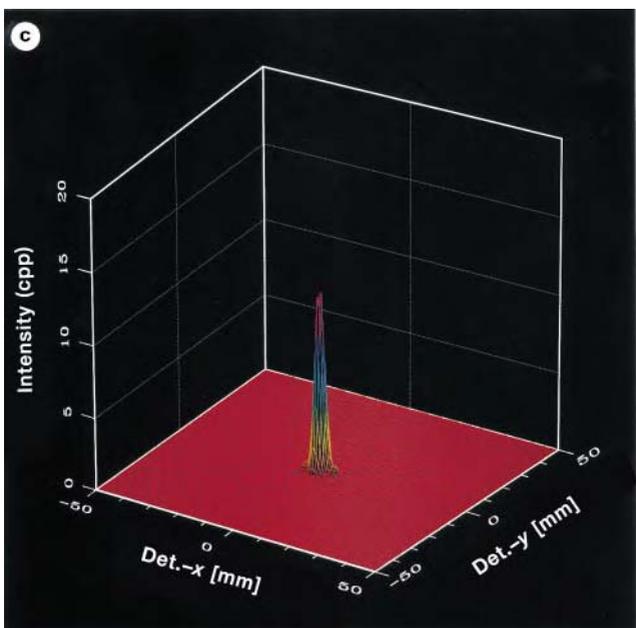

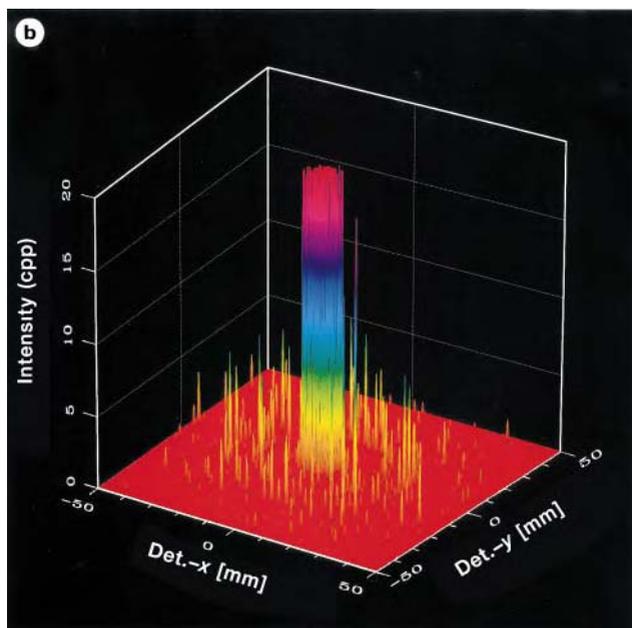

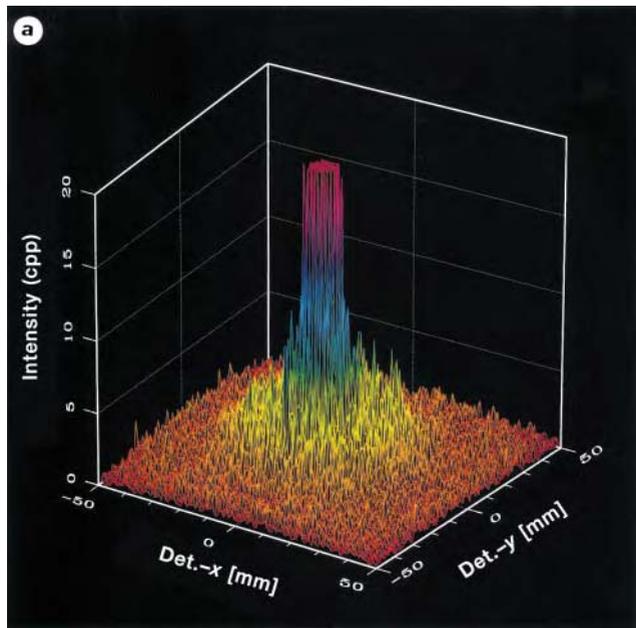

Figure 3 Elastic scattering from a variety of samples. **a–c**, Simulated diffraction images on a 128×128 pixel planar detector ($100 \text{ mm} \times 100 \text{ mm}$) normal to and centred at the beam, and placed 100 mm from the sample. The background was not modelled, and 100% detective quantum efficiency was assumed. The integrated X-ray intensity was 3×10^{12} (12 keV) photons per 100-nm diameter spot (3.8×10^6 photons per \AA^2); the pulse length was 10 fs . The resolution is 2.2 \AA at the rim in **a–c**. cpp, counts per pixel. **a**, Scattering from a single tomato bushy stunt virus capsid. **b**, Scattering from a $5 \times 5 \times 5$ cluster of lysozyme molecules with an average r.m.s. conformational deviation

of 0.2 \AA to model an imperfect lattice. **c**, Scattering from a single molecule of lysozyme. **d**, A planar section through the molecular transform (that is, a simulated continuous scattering image) of a single T4 lysozyme molecule under ideal conditions without sample movement or damage. Resolution at the rim of **d** corresponds to 2.0 \AA . Structure factor amplitudes are coloured logarithmically (magenta, high; green, low). The section is perpendicular to the z axis, and crosses through the origin at the centre of the image, revealing centric symmetry.

Single Biomolecule Imaging with XFEL

(Heterodyne Detection + Holographic Recording)

“Weak diffraction from biomolecule is amplified by 10 ~ 50 times (Heterodyne) on the coherent reference wave from nano-particle, providing 100~1000 times more photons”

T. Shintake, PR-E 78, 041906 (2008)

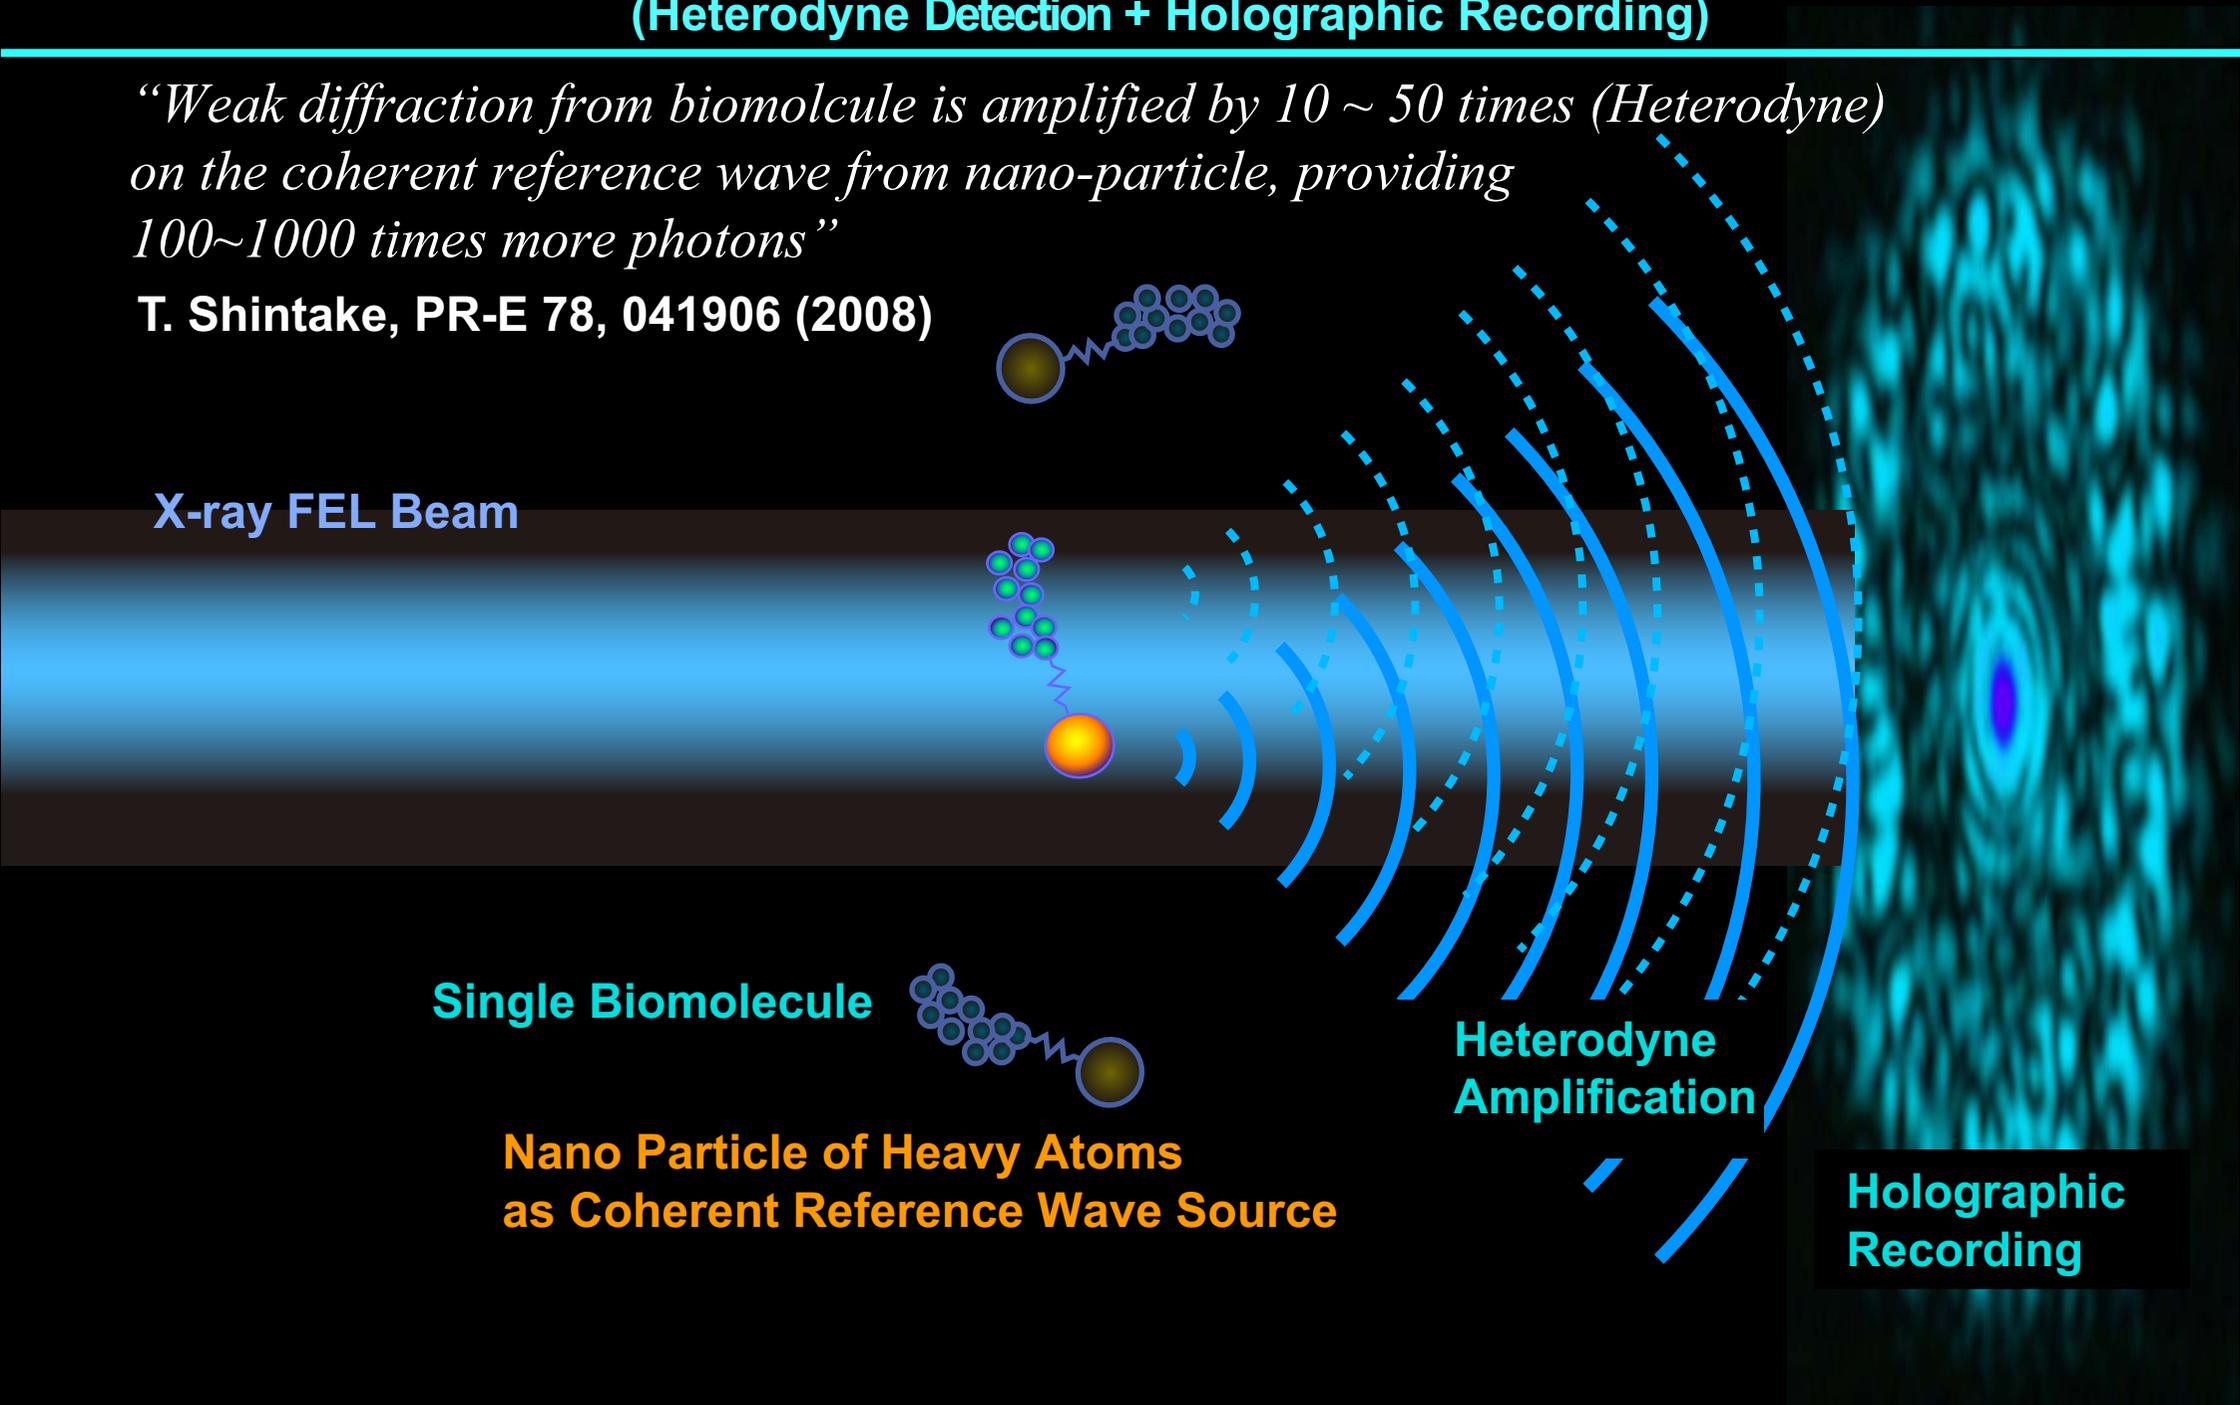

X-ray FEL Beam

Single Biomolecule

Nano Particle of Heavy Atoms
as Coherent Reference Wave Source

Heterodyne
Amplification

Holographic
Recording

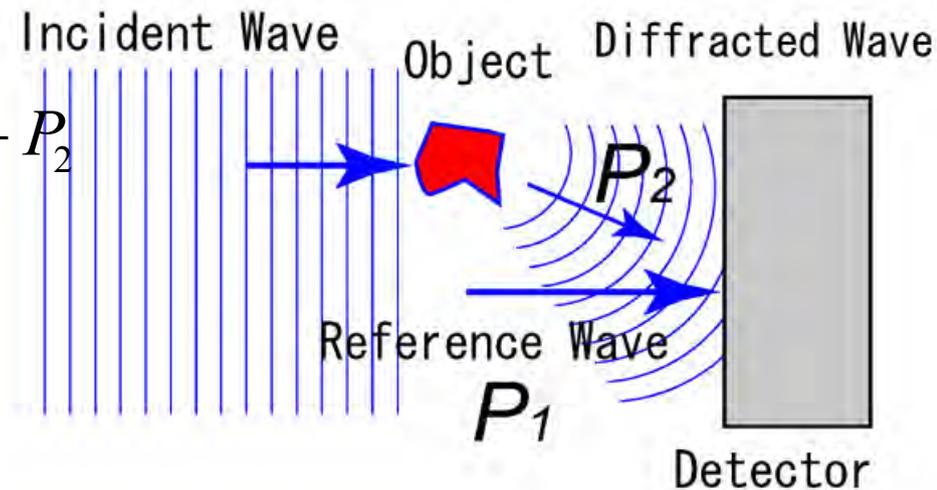

X-ray Heterodyne Detection

T. Shintake 2003

- X-ray heterodyne detection using reference X-ray P_1 on the small signal P_2*

$$\begin{aligned} P_{\pm} &= \left(\sqrt{P_1} \pm \sqrt{P_2} \right)^2 = P_1 \pm 2\sqrt{P_1 P_2} + P_2 \\ &= P_1 \left(1 \pm 2\sqrt{P_1 / P_2} + P_1 / P_2 \right) \\ &\simeq P_1 \left(1 \pm 2\sqrt{P_1 / P_2} \right) \end{aligned}$$

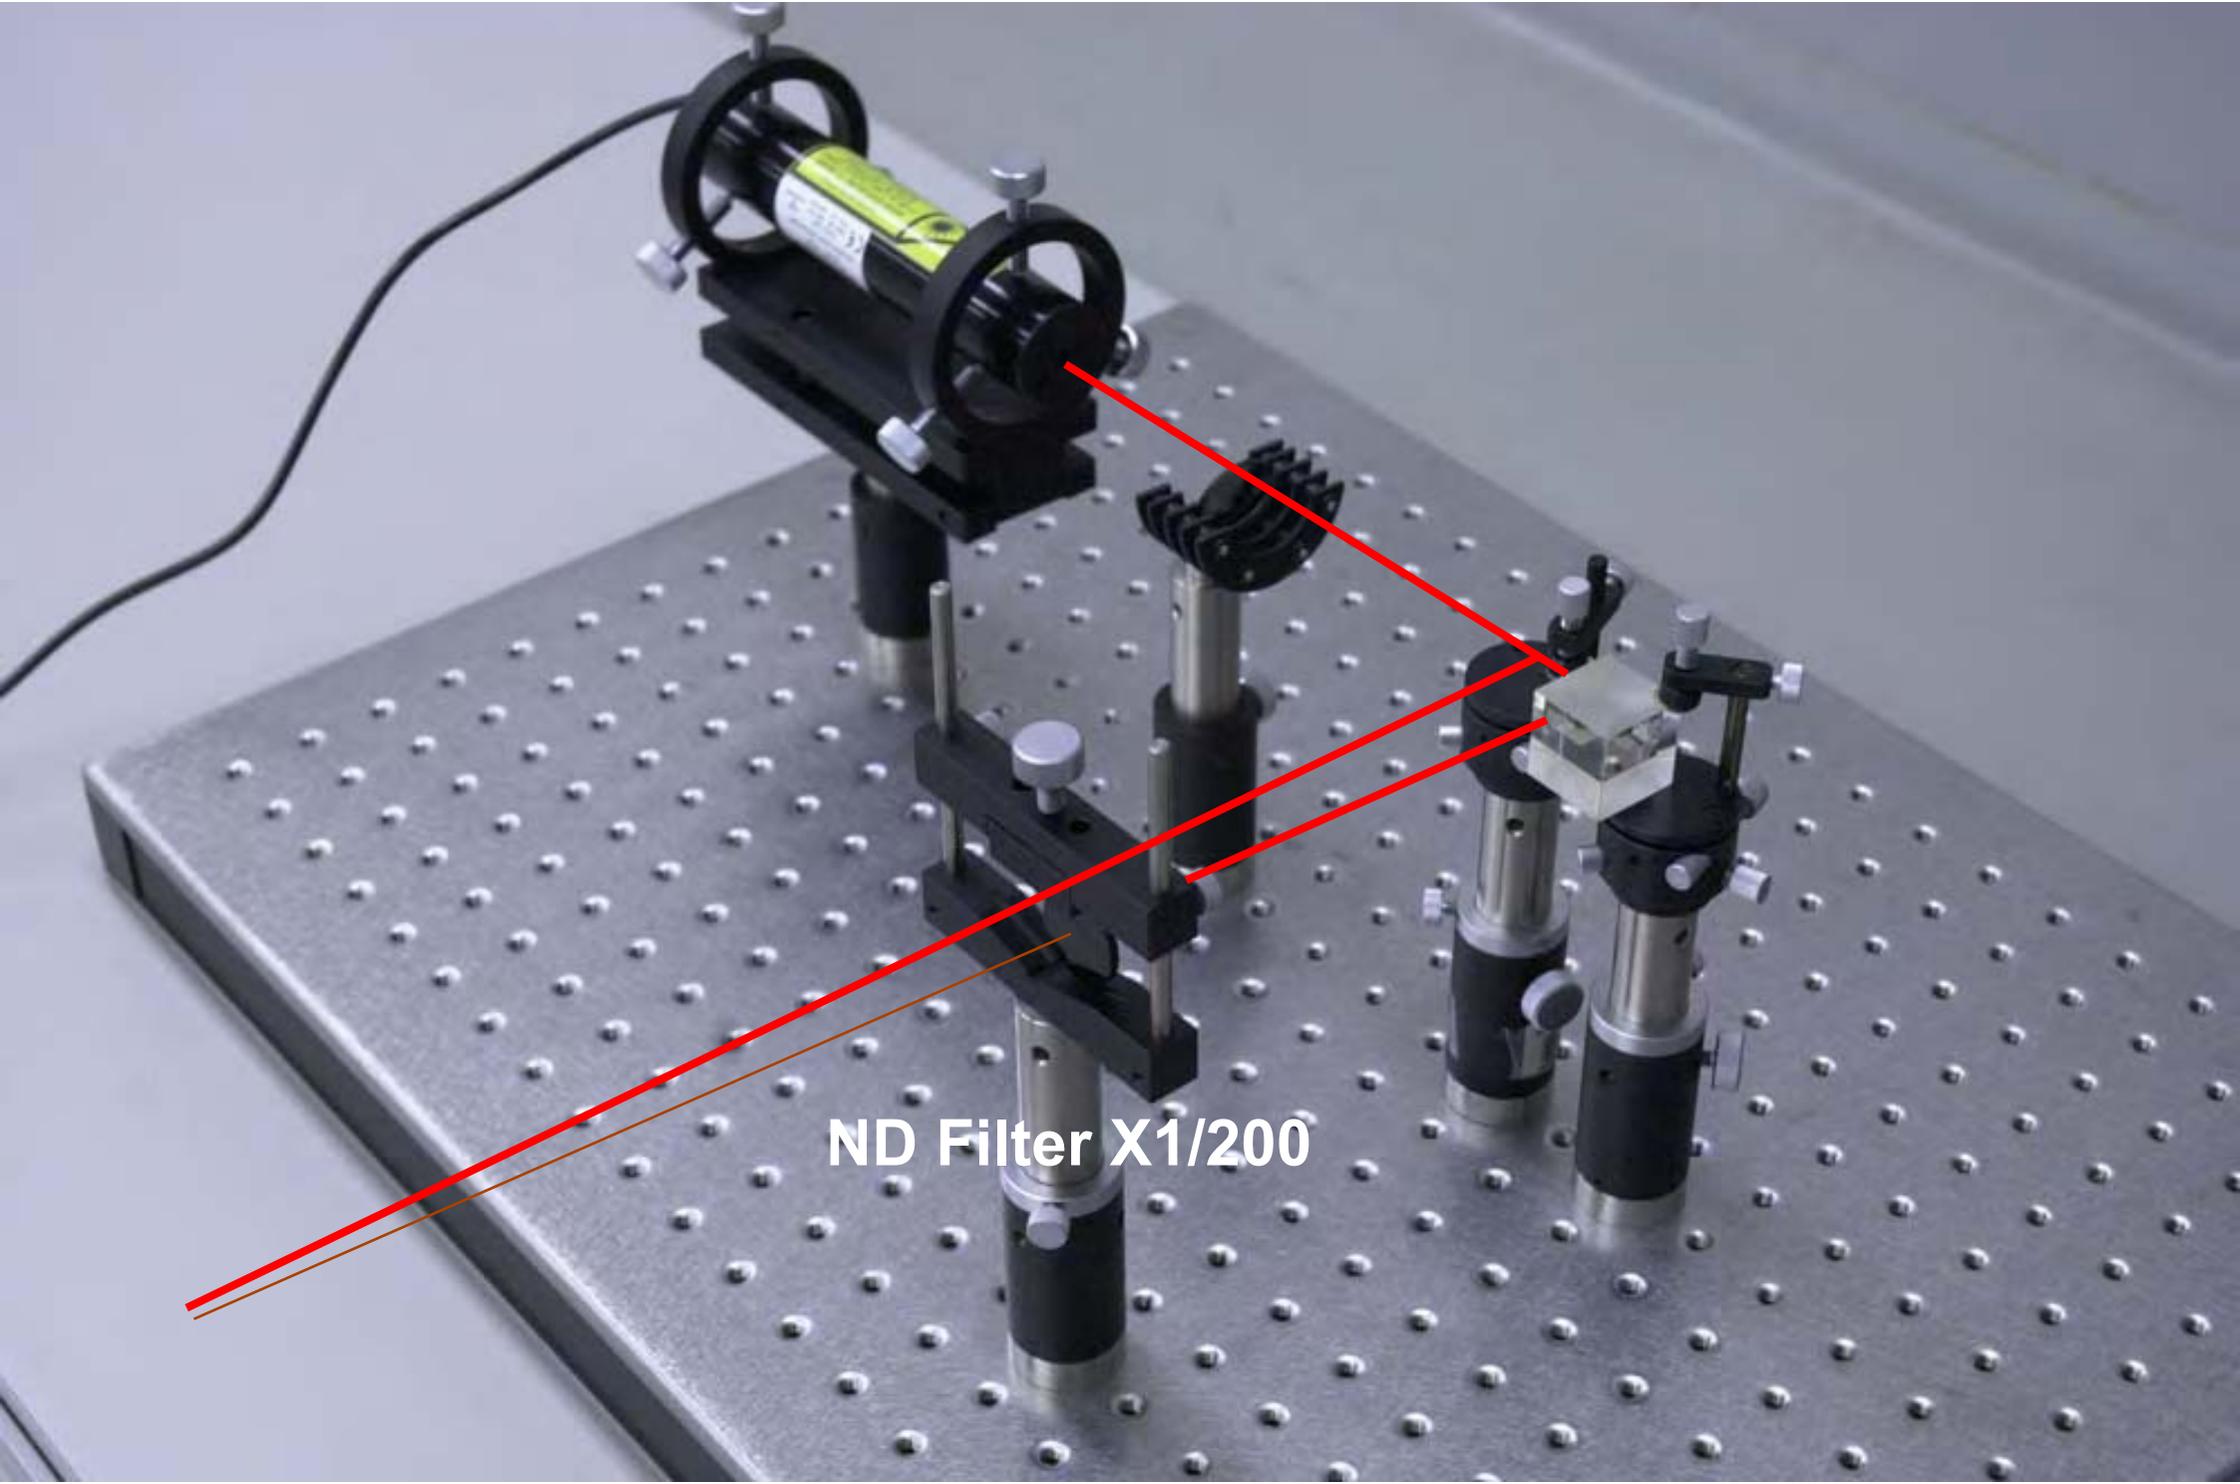

- Even if P_2 is 10^{-6} times smaller, the signal is amplified to 10^{-3} level. This is +30 dB amplification.*

Does noise increase or decrease?

- S/N due to the electrical noise in detector instrument can be easily improved as the signal growing.
- Question is the statistical noise associated with quantization of energy in photo-ionization process in CCD or film detector.
- Since amplitude of the interference pattern increase as $\propto \sqrt{I}$, and statistical noise also increases as $\propto \sqrt{I}$, thus S/N becomes constant, and **looks like** not been improved.

$$S / N \Big|_{\text{holography}} = S / N \Big|_{\text{direct}}$$

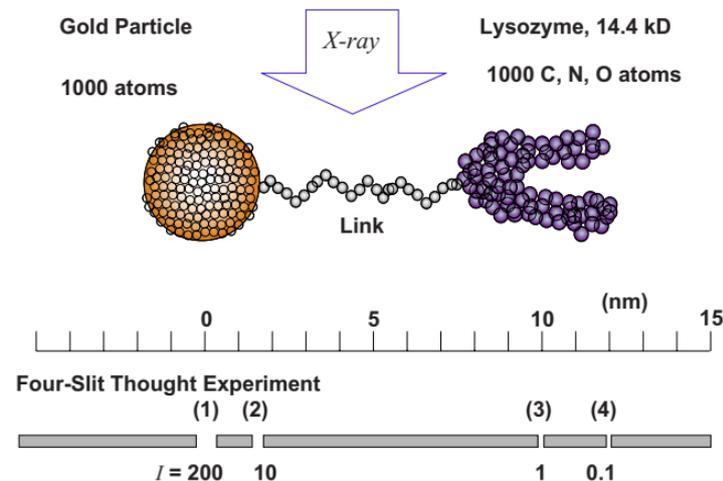

FIG. 4. (Color online) Conceptual diagram of a single lysozyme molecule linked to a gold particle (diameter of atoms is not drawn to scale). The gold particle produces 200 times more coherent x-ray scattering than the single lysozyme molecule. The bar at the bottom of the figure represents a four-slit thought experiment.

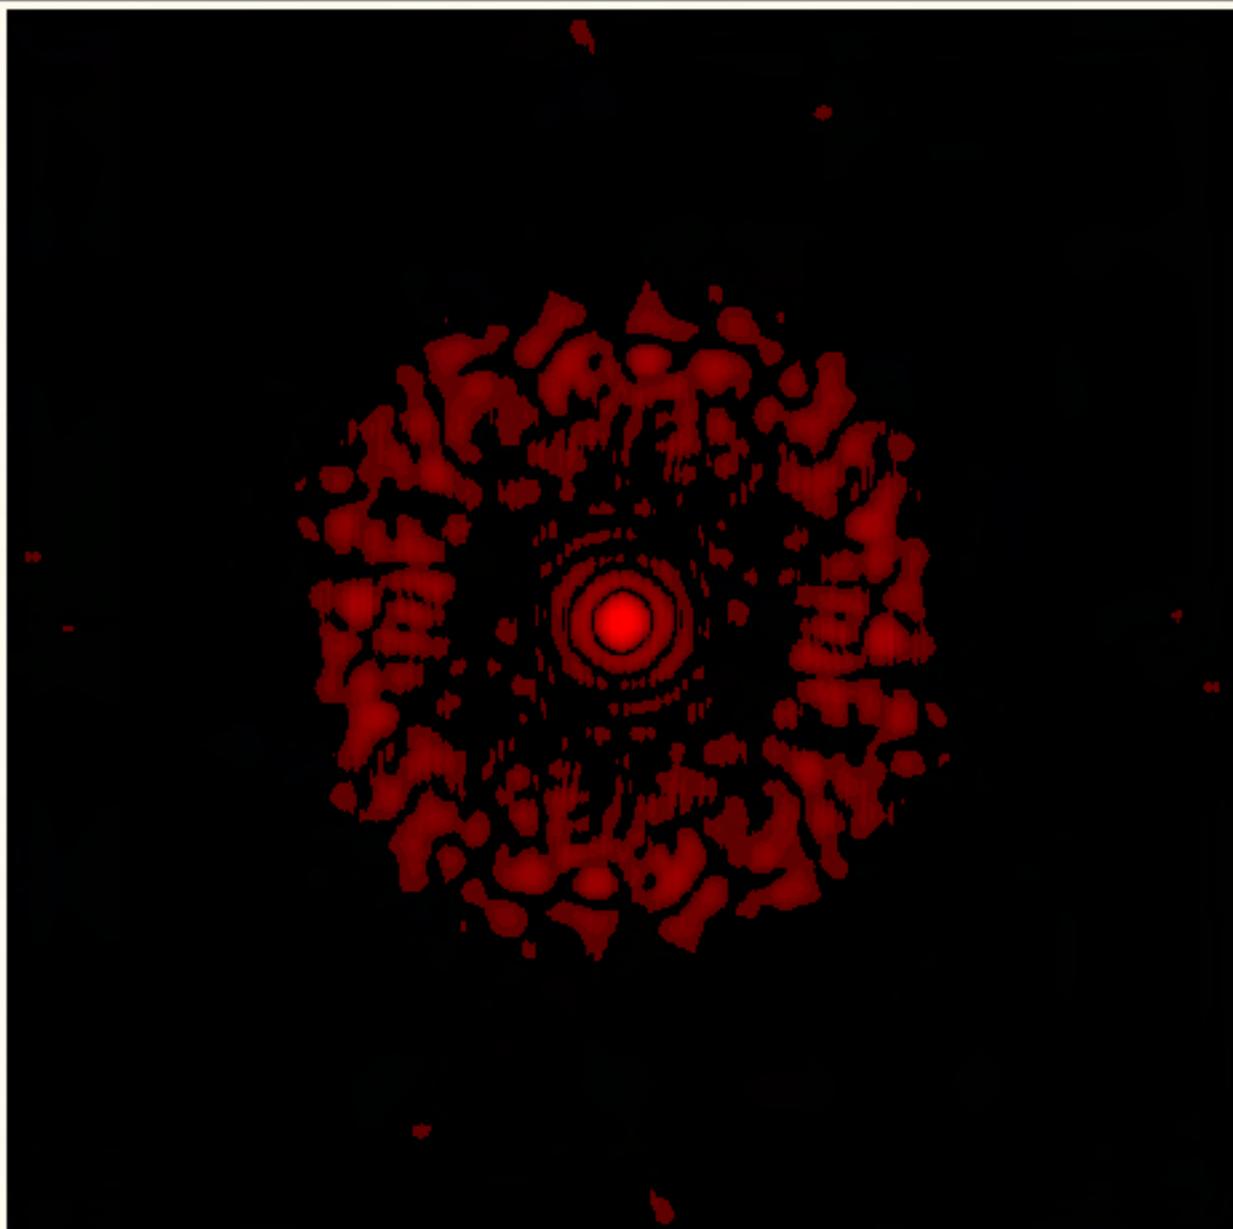

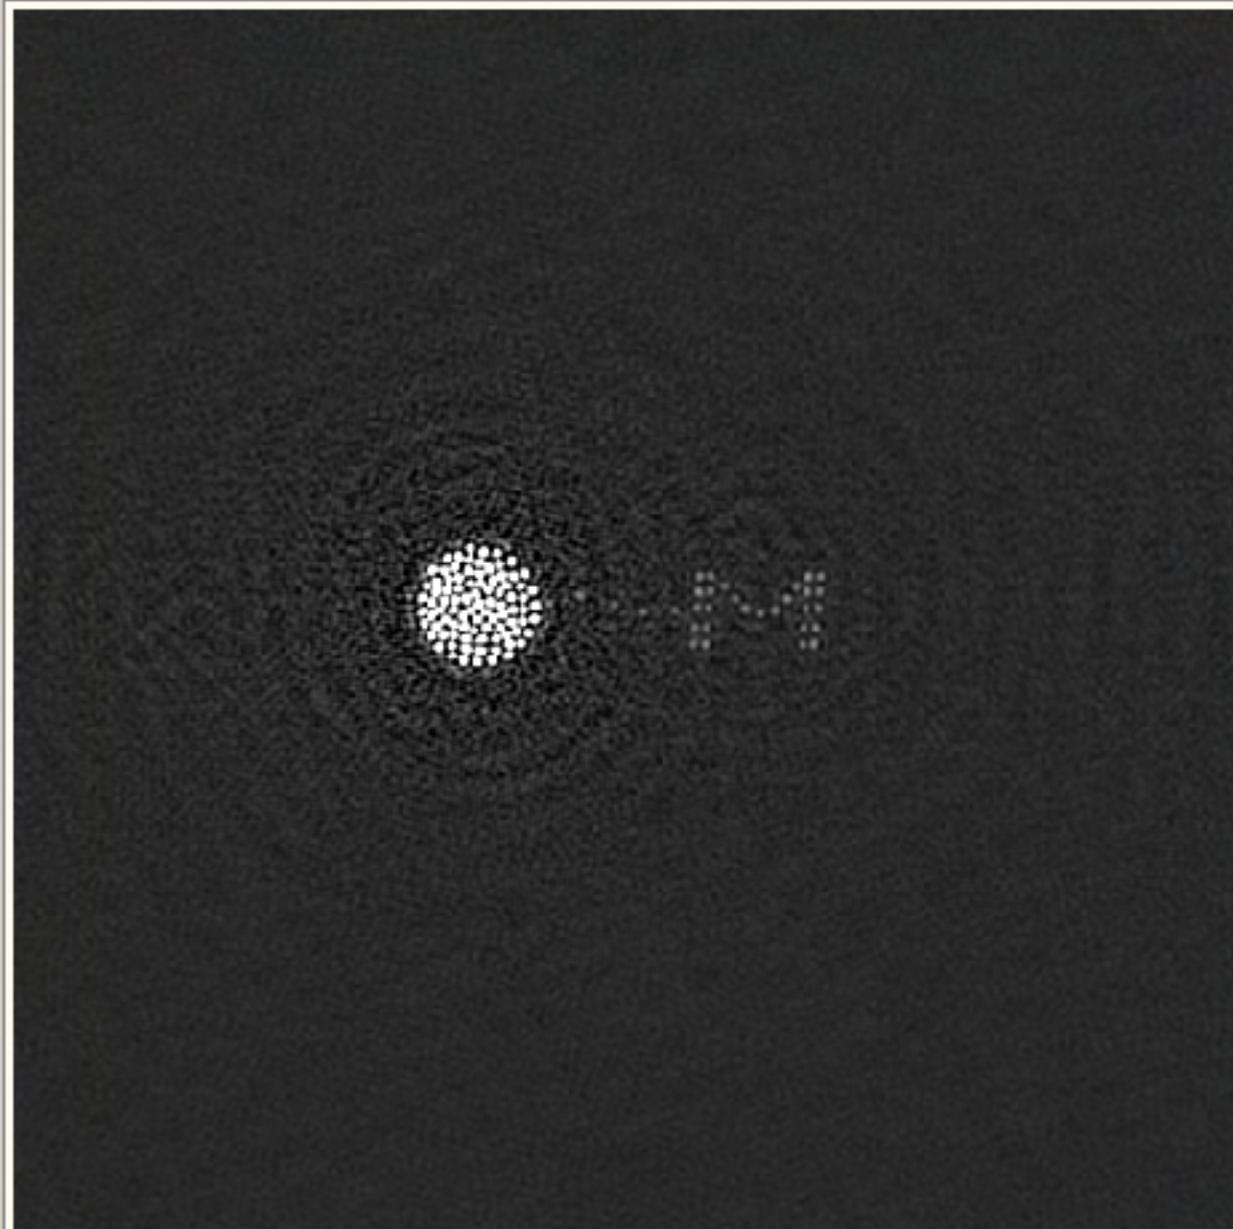

Fourier transform holography uses spherical waves as reference waves to record the phase of an object wave. The intensity of the reference wave is chosen such that it is comparable to that of the object wave to obtain the best contrast. To obtain better image quality, the size of the reference wave source should be considerably smaller than the object. The image-recovery process in Fourier transform holography is

where $\Delta\phi_{ij} = \phi_j - \phi_i$ is the phase difference given by

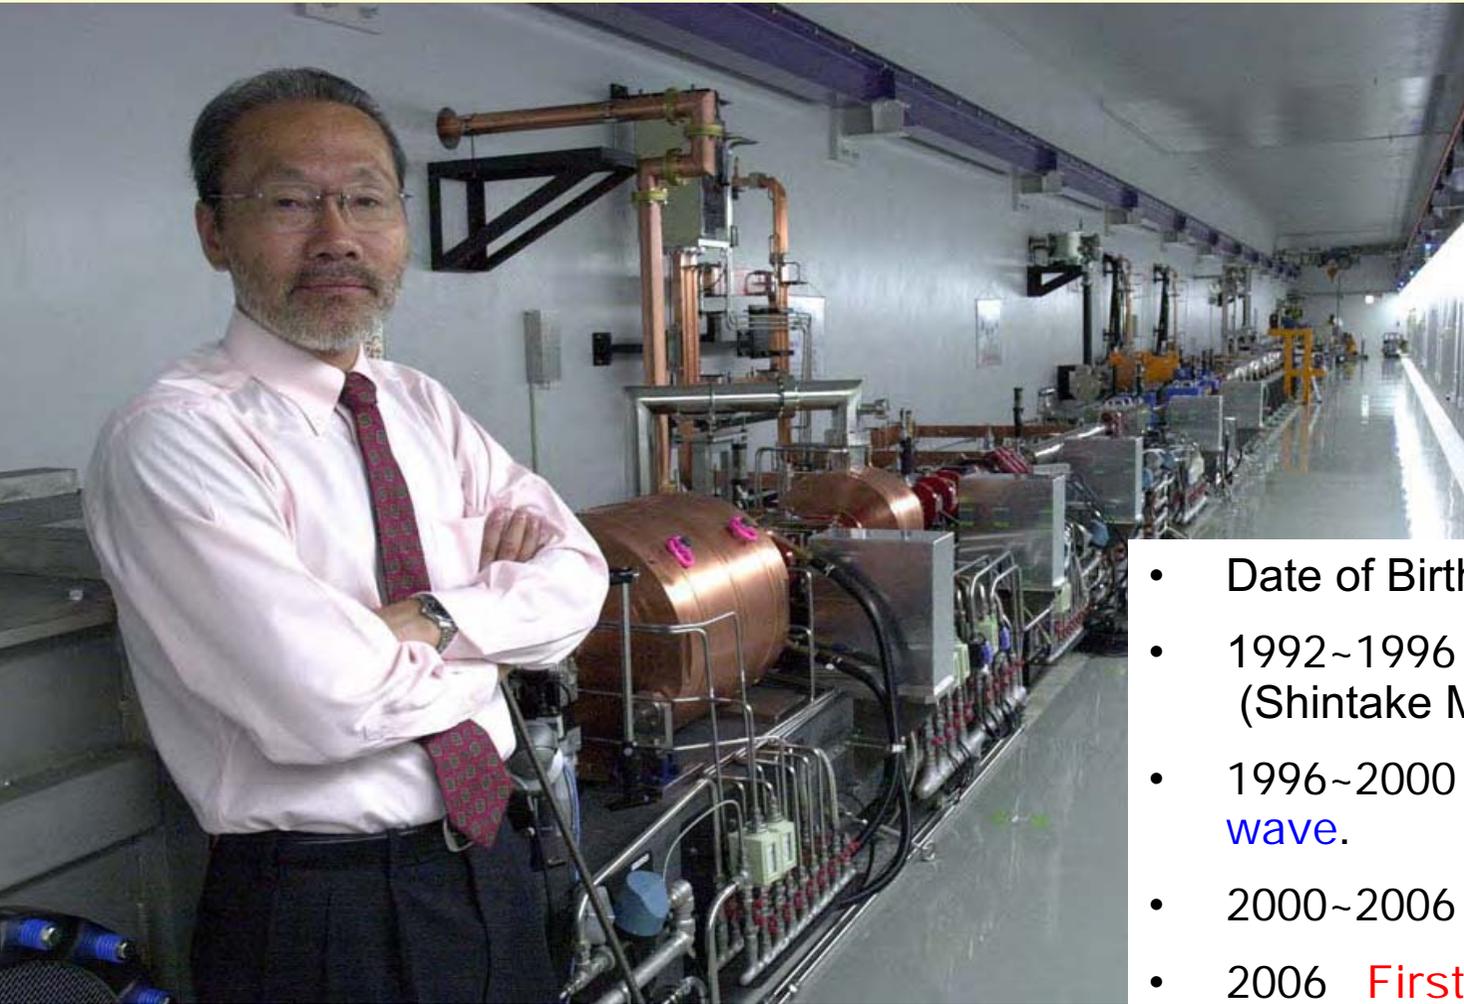

$$\Delta\phi_{ij} = \phi_j - \phi_i = \frac{2\pi d_{ij}}{\lambda} \sin(2\theta). \quad (8)$$

Here, I_i represents the flux from the i th slit, 2θ is the scattering angle (as defined in crystallography), and d_{ij} is the distance between the i and j th slits. The slit locations and flux ratio suitable for our example case shown in Fig. 4 are as follows: $d_{12} = 1.5$ nm, $d_{23} = 8.5$ nm, $d_{34} = 2$ nm, $I_1 = 200$, $I_2 = 10$, $I_3 = 1$, $I_4 = 0.1$, and $\lambda = 1$ Å. Figure 5(a) shows the flux density distribution estimated using Eq. (7). The distribution is considerably complicated because the fringes are formed by the interference of four waves.

In Fig. 5(c), the curve at the bottom indicates the scattered wave from the biomolecule when it is directly observed without using the reference pump wave. It is a very weak signal with a relative intensity of approximately 1. In practice, the signal is quantized by the photon energy, leading to a loss of detailed information. The dashed curve (magnified 10 times) also shows an interference pattern, which represents the internal structure of the biomolecule; our aim is to study this pattern. By superposition of the reference pump wave, the signal wave is amplified, and the resulting interference pattern is recorded. In order to demonstrate the amplification effect clearly, the reference pump wave is assumed to be perfect with $\psi_2 = 0$. In Fig. 5(c), the curve at the top shows the amplified signal, which is recorded by the

Summary

- So many different efforts are coherently contributing to the project. They are almost on the time schedule.
- Building construction has been completed.
- Accelerator component installation has been started.
~ 1 year installation.
- October 2010, We start high power operation of accelerator.
- Spring 2011, we start beam commissioning.
